KYRIBA TRANSFORMATION | CASE STUDY 03

Bank Statements

From bank portals to one daily cash position in Kyriba

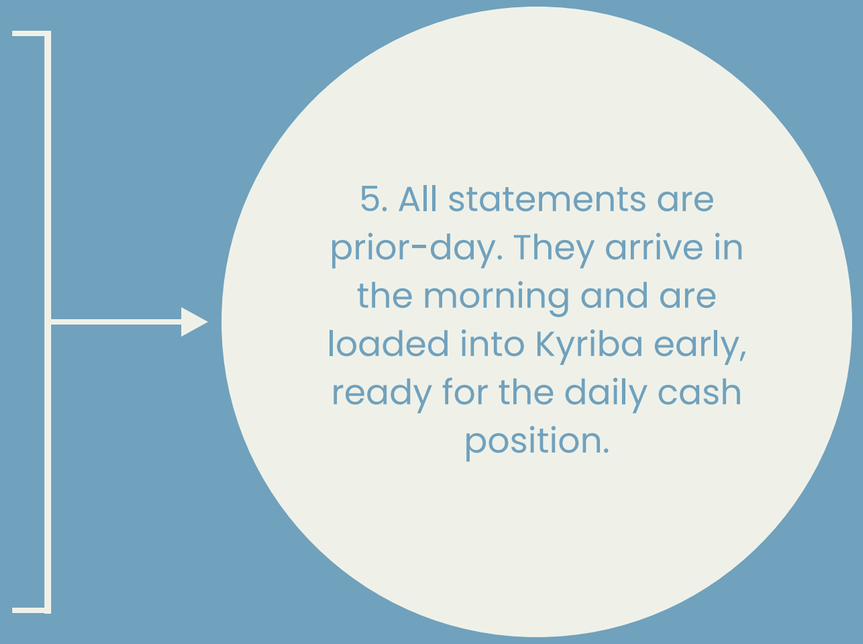

A case study in bank connectivity, transaction mapping and reconciliation.

How Bank Statements Reach Treasury

Every morning, the previous day's bank statements are loaded into Kyriba

1. Bank B is connected directly to Kyriba through EBICS and sends camt.053 statements.
2. Bank A sends MT940 statements through an external bank statement aggregator.
3. About 20 other banks send MT940 statements through the same aggregator, covering about 100 group entities in many currencies.
4. In total, about 300 bank accounts report into Kyriba.
5. Bank A and Bank B are the same core banks as in Case 02, fully connected for both payments and statements.

Before this project, statements came from bank portal downloads or SFTP files in SharePoint.

From Bank Portals to Automatic Statements

How statements, balances and reconciliation moved into Kyriba

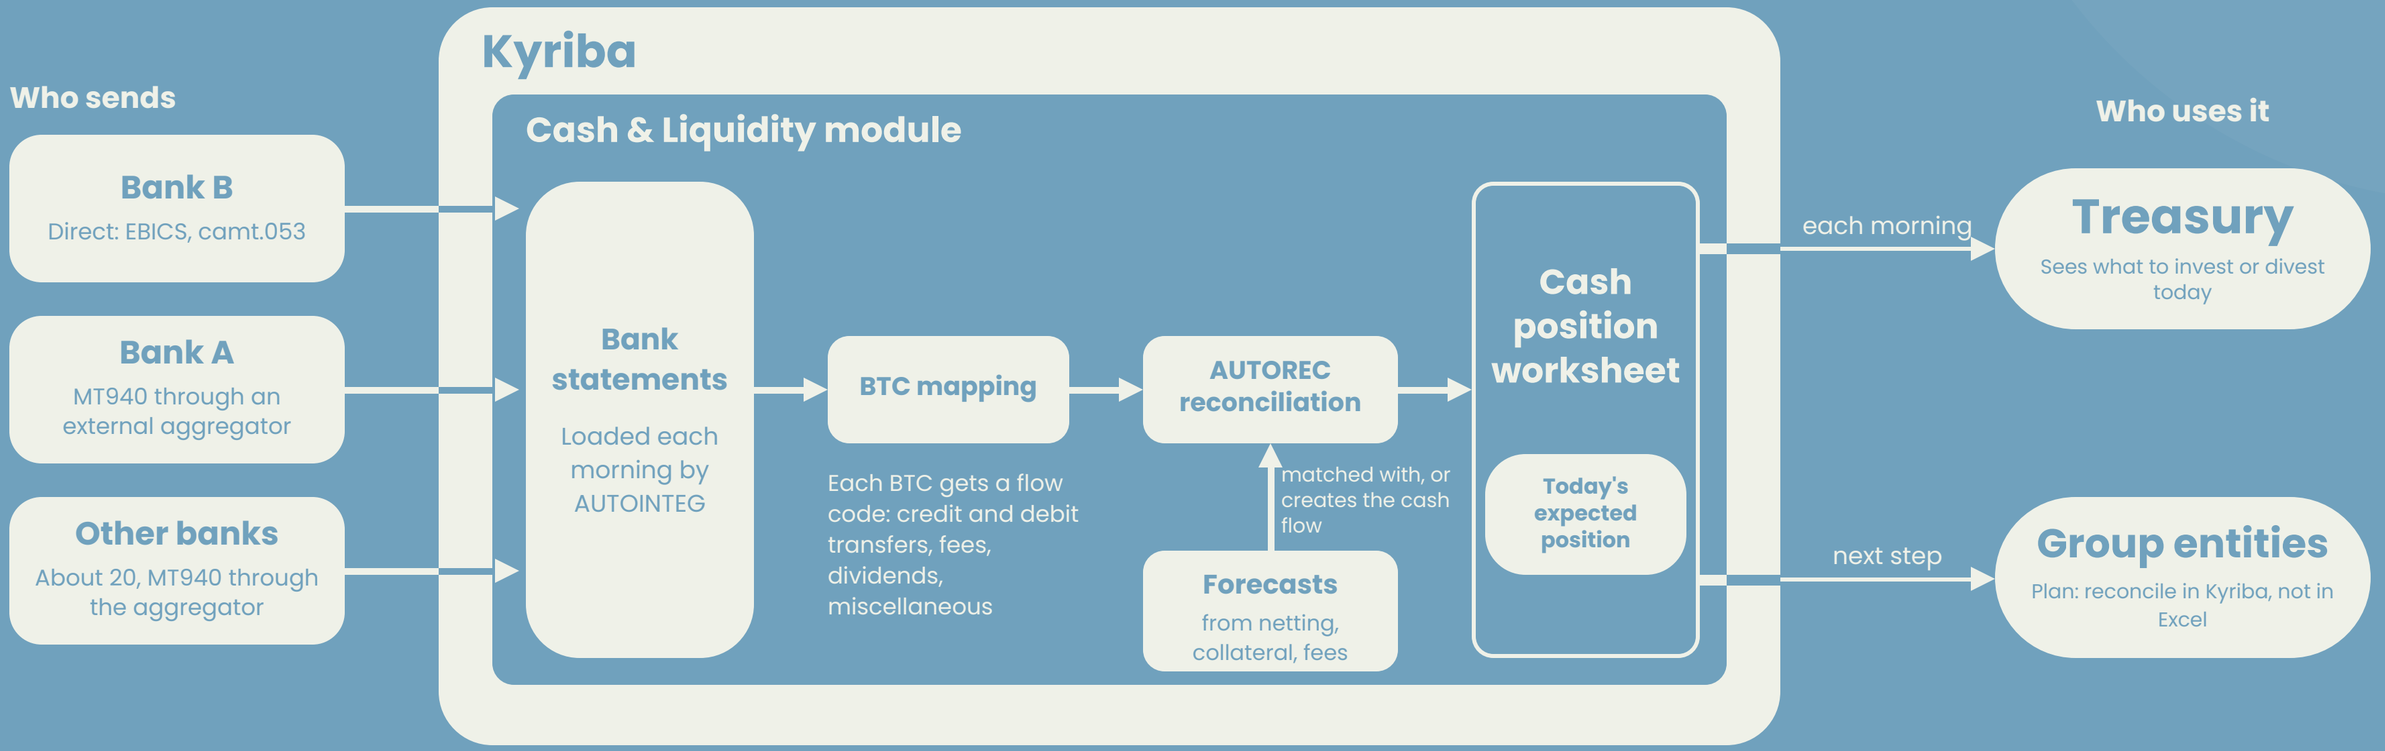

Before | Manual process

1. Many statements downloaded from bank portals
2. Some statements delivered to SharePoint through SFTP
3. Legacy TMS calculated the cash balance from its ledger, built from all financial transactions (FX, ETD, OTC derivatives, CDS, fixed income, netting, intercompany, invoices, collateral)
4. Some deals, such as collateral movements and invoices, entered by hand as journal vouchers
5. Reconciliation was a mix: by hand, or in Power BI with Dataflows connected to SharePoint

After | Statement connectivity

1. Prior-day statements arrive automatically every morning
2. Bank B direct through EBICS (camt.053); Bank A (MT940) and about 20 other banks through an external aggregator
3. Statements loaded into Kyriba early in the morning by AUTOINTEG, with balances and transactions
4. BTC mapping gives each line the correct flow code
5. Reconciliation rules (AUTOREC) match lines with the forecasts in Kyriba, or create the cash flow when there is no forecast; lines with no match go on hold for manual reconciliation
6. Today's expected cash position shows what to invest or divest

How the Statement Flow Works

1 Banks send → 2 AUTOINTEG loads → 3 BTC to flow code → 4 AUTOREC → 5 Cash position

How Reconciliation Works

AUTOREC matches statement lines with the forecasts Treasury already has in Kyriba

	Statement line	Matched with forecast from
1 Netting	TRF with "netting" in the description	Netting deal
2 Treasury transfers	Transfer between Bank A and Bank B	Treasury transfer (balancing transfer)
3 Collateral	Collateral posted	Financial transaction: collateral (variable balance)
4 RCF	RCF principal or interest	Financial transaction: RCF principal and interest
5 Fees	Fees	Intercompany fees
6 Invoices	Payment to a supplier	Third party invoice paid by Treasury
7 Money market funds	MMF subscription or redemption	Financial transaction: MMF deal (variable balance)

No forecast: AUTOREC creates the cash flow. No match: the line goes on hold for manual reconciliation.

The plan: other group entities reconcile in Kyriba instead of in Excel or by hand.

Daily Statement Checks

Four checks every morning, all in Kyriba

1

Did all statements arrive?

WHERE TO CHECK

Bank connectivity cockpit and bank connection status report

IF SOMETHING IS WRONG

Empty bank statement balance: the statement was not received. Contact the bank.

2

Were they integrated?

WHERE TO CHECK

Rejected transactions

IF SOMETHING IS WRONG

Codes 01 to 04: fix the set-up and reintegrate. Code 90: the previous day's statement is missing, contact the bank.

3

Is anything on hold?

WHERE TO CHECK

On hold column in the bank/cash balance variance report

IF SOMETHING IS WRONG

Lines with no match. Do the manual reconciliation.

4

Do bank and cash agree?

WHERE TO CHECK

Bank connectivity cockpit and bank/cash balance variance report

IF SOMETHING IS WRONG

Bank ledger and flow ledger differ. Check pending items, duplicates, manual actuals or a missing initial balance.

Only after these checks does Treasury use the cash position to invest or divest.

Business Impact

OPERATIONAL RISK

~300

bank accounts reporting automatically

Before: many statements were downloaded from bank portals or sent to SharePoint by SFTP.

EFFICIENCY

~15

minutes saved every morning on reconciliation

Before: reconciliation by hand, or in Power BI with Dataflows connected to SharePoint.

CONTROL

1

daily cash position in Kyriba

Before: the legacy TMS calculated the cash balance from its ledger of financial transactions, with some deals entered by hand.

2 core banks (Bank A and Bank B) plus about 20 other banks through an external aggregator, covering about 100 group entities.
