

KYRIBA TRANSFORMATION | CASE STUDY 01

FX Platform Integration

Reducing manual effort across a global treasury operating model

A case study in process redesign, integration, and measurable time savings.

From Manual Re-entry to Integrated Execution

How the workflow changed from fragmented handoffs to connected execution

Before | Manual process

1. Client submits FX deal in legacy TMS
1. Trader **manually** re-enters deal in Trading Platform and executes
1. Executed market trade feeds back into the legacy TMS
1. Trader **manually updates the client deal** with the FX rate and spread
1. Client **manually downloads the trade confirmation**

After | Integrated execution

1. Client submits FX deal in Kyriba; pre-trade is created
1. FX details **automatically** flow to the Trading Platform
1. Trader selects the best available deal and executes
1. Execution feeds back into Kyriba; pre-trade becomes actual trade
1. Client deal is **automatically created with spread**
1. Client **receives EOD activity email** or downloads confirmation

How the Integrated FX Workflow Operates

Kyriba connects the request, execution, trade update, and confirmation into one flow

Business Impact

Operational Risk

~99% fewer manual input errors

Manual re-entry of trade details drove ~\$4k/year in avoided rework and market-exposure risk — a conservative estimate, as costs scale with trade size.

Execution

**15 → 5 min execution time
~67% less execution time**

Automation reduces the time from client request to completed FX execution, reducing exposure to market movements.

Client Experience

**~5 min saved per deal
~15 min saved on EOD report**

A simplified Kyriba experience reduces the time for clients to submit an FX deal, while faster execution lets them move on sooner.

Additional opportunity: integrating the EOD activity email with the external administrator platform could further reduce manual follow-up.
